

Dear Vistex Hiring Team,

I'm applying for the Senior Cloud Engineer role on your Cloud Infrastructure Team. The combination of Puppet configuration management, Terraform infrastructure as code, and production Kubernetes ownership in this posting matches a career built around exactly that kind of infrastructure work.

At Tink, I managed fleet configuration as code for 600+ servers, driving all subsequent configuration and package/patch state declaratively through Puppet and Spacewalk rather than by hand — including automating OS-level patching and kernel-update reboots down to a monthly verification check with near-zero downtime. That same fleet also carried a full AWS migration target environment I built from scratch — EC2, S3, Route 53, VPC, self-managed memcached, a serverless relational database — with no prior AWS experience going in. More recently at Énergir, I led cloud modernization onto Microsoft Azure, building Terraform and Ansible IaC that eliminated configuration drift across dev, staging, and production, and at Desjardins I automated on-demand infrastructure provisioning using Kubernetes and ArgoCD.

I want to be upfront about OpenStack specifically: I haven't operated a private OpenStack cloud, though I've built and maintained production infrastructure across AWS, Azure, and on-prem VMware/Puppet-managed fleets. Given the pattern of learning unfamiliar platforms cold that runs through my career — Salesforce and Kubernetes at Énergir and Desjardins, AWS at Tink — I'm confident I can get productive on OpenStack quickly, and I'd rather say that plainly than imply experience I don't have.

I'd welcome the opportunity to discuss how this background applies to Vistex's cloud infrastructure. Thank you for your consideration.

Sincerely, Marc Berthelette
